Summary

This talk (or design doc) briefly covers some internal design decisions of Taichi, for developers and users who want to dig deeper into Taichi. Topics include

- How does Taichi work?
- Why do we end up the current design decisions?
- What do I need to know to improve Taichi?

Setting up Taichi locally

- Installation via pip: `python3 -m pip install taichi`
- Building from source (or Docker) for development: [►doc:Developer installation](#)

Pick one installation only

Avoid having both pip-installed Taichi and the version build from source.

Summary

High-performance domain-specific language (DSL) embedded in **Python**, for **computer graphics** applications

- **Productivity** and **portability**: easy to learn, to write, and to share
- **Performance**: data-oriented, parallel, megakernels
- **Spatially sparse** programming: save computation and storage on empty regions
- **Decouple** data structures from computation
- **Differentiable** programming support
- **Quantized** computation support

Taichi v.s. deep learning frameworks

[Summary](#)

Why is Taichi different from TensorFlow, PyTorch, NumPy, JAX, ... ?

Quick answer: Taichi uniquely supports **programmable megakernels** and other graphics-oriented features such as **spatial sparsity**.

Longer answer: Those systems serve their own application domains (e.g., convolutional neural networks) very well, but their design decisions surrounding *immutable, dense tensors* (e.g., feature maps) with *element-wise or pre-programmed* operations (e.g., add and convolutions) do not serve well more irregular computational patterns, such as

- Computer graphics, including physical simulation and rendering
- Irregular neural network layers (e.g., gathering/scattering)
- General differentiable programming cases

Without Taichi people tend to manually write CUDA or abuse deep learning programming interfaces. Taichi offers performance, productivity, and portability in those cases.

Runtime system

Summary

Taichi's old C++ frontend

Taichi used to be embedded in C++14. However, that solution is mostly abandoned, because

- ① C++ itself is too complex for most users to learn, not to say a DSL embedded in C++. E.g., ►math/svd.h ☹
- ② Getting C++ AST is almost impossible. We had to heavily use templates/macros tricks, which harm readability. ☹

Taichi's new Python frontend

Now the whole Taichi system is deeply embedded in Python.

- ① Python is easy to learn and widely adopted. ☺
- ② Python allows flexible AST inspection and manipulation. ☺

Both of these allow us to invent a new high-performance language out of Python.

Other goodies of the Python frontend

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend

Intermediate
representation
Computation IR
Structural node IR

Sparse
programming

Differentiable
programming

Backends
Runtime system

Summary

- Easy to run. No ahead-of-time compilation is needed.
- Reuse and interact with existing python infrastructure:
 - ① IDEs such as PyCharm.
 - ② Package manager (pip)
 - ③ Existing packages such as `matplotlib` and `numpy`
- The built-in AST manipulation tools (`import ast`) in python allow us to do magical things, as long as the kernel body can be parsed by the Python parser.

Kernels marked with `@ti.kernel` will be compiled into a Taichi AST and then to parallel kernels on CPU/GPUs.

Runtime system

Summary

(i) Taichi kernel (Python) → Taichi AST generator (Python)

Taichi has a series of Python AST transformers `►lang/transformer.py` that transforms a Taichi kernel (in Python) into another Python script, which is a Taichi AST generator.

(ii) Taichi AST generator (Python) → Taichi AST (C++)

The Taichi AST generator is a Python script that calls AST builder functions in C++ (exported via pybind11) when executed. The result of this step is a Taichi AST.

Confused? Let's take a look at an example 😊

Generating a Taichi AST (example)

Life of a Taichi
Kernel

Yuanming Hu

Introduction

Python frontend

Intermediate
representation

Computation IR
Structural node IR

Sparse
programming

Differentiable

Taichi intermediate representation (IR): Two components

Life of a Taichi
Kernel

Yuanming Hu

Introduction

Python frontend

Intermediate
representation

Computation IR

Structural node IR

Sparse
programming

Differentiable
programming

Backends

Runtime system

Summary

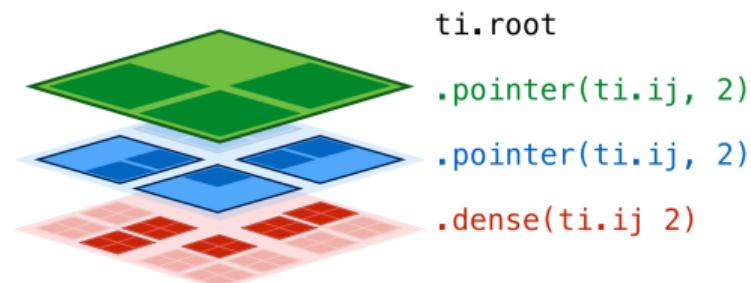

1. Computation IR

- Static-single assignment
- Hierarchical (instead of CFG+BB)
- Differentiable
- Statically and strongly typed

```
$0 = offloaded range_for(0, 10)
body {
    <i32 x1> $1 = loop $0 index 0
    <i32 x1> $2 = const [3]
    <i32 x1> $3 = cmp_eq $1 $2
    <i32 x1> $4 = const [1]
    <i32 x1> $5 = bit_and $3 $4
    $6 : if $5 {
        print $1, "\n"
    }
}
```

2. Structural Node (SNode) IR

- Describes data organization
- Tree-structured
- Spatial sparsity
- Favors powers of two

IR design goals: a) enable domain-specific optimizations for sparse computation.
b) decouple data layout from computation (more on this later).

Progressive compilation

Life of a Taichi Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming
Differentiable programming
Backends
Runtime system
Summary

- ① Taichi compiler progressively compiles a frontend AST into executable CPU/GPU kernels.
- ② During this process, 30+ compilation passes are applied to the Taichi AST/IR.
- ③ The only big step is from Taichi AST to Taichi IR (AST lowering
►[transforms/lower_ast.cpp](#)), where two different sets of statements (instructions) are used.
- ④ Each other pass makes a small step towards hardware-friendly code only.
Almost the same sets of statements are used for input/output Taichi IR.
- ⑤ There is **no** clear separation of IR statements (e.g. high-level, mid-level, low-level IR) after AST lowering.

10 key compilation passes

Taichi's IR transformation passes gradually converts an input Taichi AST to parallel executable kernels [►transforms/compile_to_offloads.cpp](#).

① Taichi frontend AST to Taichi IR

- ① Lower Taichi AST to SSA [►transforms/lower_ast.cpp](#)
- ② Type checking [►transforms/type_check.cpp](#)

② Taichi IR to offloaded tasks

- ① (Optional) Automatic differentiation [►transforms/auto_diff.cpp](#)
- ② (Optional) Insert bound checks [►transforms/check_out_of_bound.cpp](#)
- ③ Flag and weaken access [►transforms/flag_access.cpp](#)
- ④ Automatic parallelization [►transforms/offload.cpp](#)

③ Offloaded tasks to executable

- ① Demote dense struct-fors to range-fors
[►transforms/demote_dense_struct_fors.cpp](#)
- ② Create thread local storage [►transforms/make_thread_local.cpp](#)
- ③ Create block local storage [►transforms/make_block_local.cpp](#)
- ④ Lower access [►transforms/lower_access.cpp](#)

(Optimization passes are skipped to save space)

Statements

Life of a Taichi Kernel
Yuanming Hu
[Introduction](#)
[Python frontend](#)
[Intermediate representation](#)
[Computation IR](#)
Structural node IR
[Sparse programming](#)
[Differentiable programming](#)
[Backends](#)
Runtime system
[Summary](#)

Taichi IR has ~ 70 statements.

Typical statements include:

- Arithmetic [►ir/ir.h](#)
 - ① UnaryOpStmt. Operators [►inc/unary_op.inc.h](#) (sqrt, sin, ...)
 - ② BinaryOpStmt. Operators [►inc/binary_op.inc.h](#) (add, mul, ...)
 - ③ ...
- Memory access: Global[Ptr/Load/Store]Stmt
- AutoDiff Stack operations (more on this later):
`Stack[Alloca/LoadTop/LoadTopAdj/Pop/Push/AccAdjoint]Stmt`
- SNode Micro Ops (after the `lower_access` pass)
- ...

General-purpose optimization passes

Runtime system
Summary

Why optimize Taichi IR? Can't we leave the job to LLVM?

Quick answer:

- Higher optimization quality (next slide)
- Fewer instructions to LLVM: faster JIT

General-purpose optimization passes

- Control-flow based optimizations: CSE, DIE, ...
► [transforms/cfg_optimization.cpp](#)
- Constant folding ► [transforms/constant_fold.cpp](#) (more details later)
- Algebraic simplification ► [transforms/alg_simp.cpp](#)
- ...

programming

Differentiable
programming

Backends
Runtime system

Summary

Long story short: backend compilers (e.g., LLVM) do not have as much information as the Taichi compiler do.

For example, Taichi IR and optimizer

- ① ...can do index analysis
- ② ...have a tailored instruction granularity
- ③ ...have strict data access semantics

Therefore traditional compilers often fail to do certain important optimizations.

Benchmarks show Taichi IR optimization passes (mostly on data accesses) make programs 3.02× faster¹, even if we use -O3 on backend compilers.

Differentiable programming
Backends
Runtime system
Summary

Seemingly trivial assumptions can enable effective compiler optimization and make programmers' life easier. E.g.,

- ① No pointer aliasing: `a[x, y]` and `b[i, j]` never overlaps unless `a` and `b` are the same field [►analysis/alias_analysis.cpp](#)
- ② All memory accesses are done through `field[indices]` syntax
 - Pointers that can flexibly point to anything arguably makes optimization harder
- ③ The only way data structures get modified, is through write accesses of form `field[indices]`
- ④ Read access **does not** modify anything
 - No memory allocation
 - No exception if element does not exist

Example general-purpose opt pass: Constant folding

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming

Differentiable programming

Backends
Runtime system
Summary

Taichi's constant folding pass uses JIT evaluation on the device

► [transforms/constant_fold.cpp](#)

- ① Generate a small Taichi kernel that only does the simple unary/binary operation. E.g, `f32 + f32`.
- ② Evaluate the small kernel on operands
- ③ Replace the arithmetic statement with a constant statement with value being the result.

Evaluating on the device for correctness

Certain operations (e.g., `sin(x)`) on host evaluation (e.g., x64) may generate a different result from device (e.g., OpenGL) evaluation.

For correctness, do constant folding evaluation on devices. (... and assume no `fastmath`.)

Offloading (automatic parallelization)

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming
Differentiable programming
Backends
Runtime system
Summary

The offload pass [►transforms/offload.cpp](#) decomposes kernels into **offloaded statements** (`OffloadedStmt`). Each `OffloadedStmt` have one of the following types:

- ① `serial`: Simple serial code
- ② `range_for`: Parallel range-for
- ③ `clear_list`: Clear the list of nodes for `struct_for`
- ④ `listgen`: Generate list of nodes for `struct_for`
- ⑤ `struct_for`: Parallel struct-for
- ⑥ `gc`: Garbage collection

Summary

CUDA

A screenshot of a code editor displaying multiple CUDA kernel files. The files contain complex C++ code with CUDA-specific syntax like __global__ functions and memory management. The code appears to be for a physics simulation, involving particle interactions and grid calculations.

Taichi

```
ti.cache_shared(grid_m, grid_v)
for I in ti.gropued(pid): # Particle state update and scatter to grid (P2G)
    p = pid[I]
    base = ((x[p] + Offset) * inv_dx - 0.5).cast(int)
    for d in ti.static(range(3)):
        base[d] = ti.assume_in_range(base[d], I[d], 0, 1)
        fx = (x[p] + Offset) * inv_dx - base.cast(float)
        w = [0.5 * ti.sqr(1.5 - fx), 0.75 - ti.sqr(fx - 1), 0.5 * ti.sqr(fx - 0.5)]
        stress = ...
        stress = (-dt * p.vol * 4 * inv_dx * inv_dx) * stress
        affine = stress + p.mass * C[p]
        for i, j, k in ti.static(ti.ndrange(3, 3, 3)): # Loop over 3x3x3 grid
            offset = ti.Vector([i, j, k])
            dpos = (offset.cast(float) - fx) * dx
            weight = w[i][0] * w[j][1] * w[k][2]
            grid_v[base + offset] += weight * (p.mass * v[p] + affine @ dpos)
            grid_m[base + offset] += weight * p.mass
```

Data types

Yuanming Hu

Introduction

Python frontend

Intermediate
representation

Computation IR

Structural node IR

Sparse
programming

Differentiable
programming

Backends

Runtime system

Summary

Taichi is statically and strongly typed. Supported types include

- Signed integers: `ti.i8/i16/i32/i64`
- Unsigned integers: `ti.u8/u16/u32/u64`
- Float-point numbers: `ti.f32/f64`

`ti.i32` and `ti.f32` are the most commonly used types in Taichi. Boolean values are represented by `ti.i32` for now.

Data type compatibility

The CPU and CUDA backends support all data types. Other backend may miss certain data type support due to backend API constraints. See the documentation for more details.

Fields

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming
Differentiable programming
Backends
Runtime system
Summary

Taichi is a *data-oriented* programming language where **fields** are first-class citizens.

- Fields are essentially multi-dimensional arrays
- An element of a field can be either a scalar (`ti.field`), a vector (`ti.Vector.field`), or a matrix (`ti.Matrix.field`)
- Field elements are *always* accessed via the `a[i, j, k]` syntax. (No pointers.)
- Access out-of-bound is undefined behavior in non-debug mode
- *(Advanced) Fields can be spatially sparse*

Manipulating data layouts

Life of a Taichi
Kernel

Yuanming Hu

Introduction

Python frontend

Intermediate
representation

Computation IR
Structural node IR

Sparse
programming

Differentiable
programming

Backends

Runtime system

Summary

- **Data layout** refers to the dimensionality, shape, memory layout, and sparsity structure of fields.
- A carefully designed data layout can significantly improve cache/TLB-hit rates and cacheline utilization.
- Taichi decouples algorithms from data layouts, and the Taichi compiler automatically optimizes data accesses on a specific data layout.
- These Taichi features allow programmers to quickly experiment with different data layouts and figure out the most efficient one on a specific task and computer architecture.
- In Taichi, the layout is defined in a recursive manner.

(From now on we focus on scalar fields `ti.field`.)

Data layout in three languages

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming
Differentiable programming

Runtime system
Summary

Taichi (Python)

```
x = ti.field(dtype=ti.i32);  
ti.root.dense(ti.i, 16).place(x)
```

Equivalent C++

```
int x[16];
```

Natural language

- `ti.root` is the root data structure.
- Dot (`A.B`) means “Each cell of `A` has `B`”
- `dense(ti.i, 16)` means “a `dense` container with 16 cells along the `ti.i` axis”
- `place` means “... `field` ...”

**“Each cell of `root` has a `dense` container with 16 cells along the `ti.i` axis.
Each cell of `dense` has `field` `x`.”**

More data layouts

Summary

Structure of arrays (SOA):

Taichi (Python)

```
ti.root.dense(ti.i, 16).place(x)
ti.root.dense(ti.i, 16).place(y)
```

Array of structures (AOS):

Taichi (Python)

```
ti.root.dense(ti.i, 16).place(x, y)
# or equivalently
point = ti.root.dense(ti.i, 16)
point.place(x)
point.place(y)
```

Equivalent C++

```
int x[16];
int y[16];
```

Equivalent C++

```
struct Point {int x, y}
Point points[16];
```

Nesting: Array of structures of arrays (AOsoA) example

Taichi (Python)

```
chunk = ti.root.dense(ti.i, 2)  
  
chunk.dense(ti.i, 8).place(x)  
chunk.dense(ti.i, 8).place(y)
```

Equivalent C++

```
struct PointChunk {  
    int x[8]; int y[8];  
};  
PointChunk points[2];
```

Discussions

In Taichi, you can always access `x` and `y` using syntax like `x[5]` or `y[7]`.
In C++ the access is data-layout dependent.

This is just for dense data. For sparse data it is even trickier in C++.

Higher dimensionality

[Summary](#)

Currently supported SNode types ▶ [inc/snodes.inc.h](#):

- ① `root`: The root of the data structure.
- ② `dense`: A fixed-length contiguous array.
- ③ `bitmasked`: similar to `dense`, but it also uses a mask to maintain sparsity information, one bit per child.
- ④ `pointer`: Store pointers instead of the whole structure to save memory and maintain sparsity.
- ⑤ `dynamic`: Variable-length array, with a predefined maximum length. It serves the role of `std::vector` in C++ or `list` in Python.

Summary

Ideally...

Save memory and computation on inactive spaces.

Reality...

Not easy to achieve desired performance and productivity

Taichi's solutions

- ① Allow programmers to flexibly define sparse data structures using SNodes
- ② Let programmers access sparse data structures as if they are dense
- ③ Automatically manage memory
- ④ Taichi's compiler automatically optimizes sparse data structure access

People's favorite sparse SNode

Sparse
programming

Differentiable
programming

Backends
Runtime system

Summary

Forward programs evaluate $f(\mathbf{x})$; backward (gradient) programs evaluate $\frac{\partial f(\mathbf{x})}{\partial \mathbf{x}}$.

Taichi supports **reverse-mode automatic differentiation (AutoDiff)** that back-propagates gradients w.r.t. a scalar (loss) function $f(\mathbf{x})$.

Two ways to compute gradients:

- ① Use Taichi's tape (`ti.Tape(loss)`) for both forward and gradient evaluation.
- ② Explicitly use **gradient kernels** for gradient evaluation with more controls.

Gradient-based optimization

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming
Differentiable programming
Backends
Runtime system
Summary

$$\min_{\mathbf{x}} \quad L(\mathbf{x}) = \frac{1}{2} \sum_{i=0}^{n-1} (\mathbf{x}_i - \mathbf{y}_i)^2.$$

- ① Allocating fields with gradients:

```
x = ti.field(dtype=ti.f32, shape=n, needs_grad=True)
```

- ② Defining loss function kernel(s):

```
@ti.kernel
def reduce():
    for i in range(n):
        L[None] += 0.5 * (x[i] - y[i])**2
```

- ③ Compute loss with `ti.Tape(loss=L): reduce()`

- ④ Gradient descent: `for i in x: x[i] -= x.grad[i] * 0.1`

Demo: `ti` example autodiff_minimization

Another demo: `ti` example autodiff_regression

Application 1: Forces from potential energy gradients

Life of a Taichi Kernel
Yuanming Hu
[Introduction](#)
[Python frontend](#)
[Intermediate representation](#)
Computation IR
Structural node IR
[Sparse programming](#)
[Differentiable programming](#)
[Backends](#)
Runtime system
[Summary](#)

From the definition of potential energy:

$$\mathbf{f}_i = -\frac{\partial U(\mathbf{x})}{\partial \mathbf{x}_i}$$

Manually deriving gradients is hard. Let's use AutoDiff:

- ① Allocate a 0D field to store the potential energy:

```
potential = ti.field(ti.f32, shape=())
```

- ② Define forward kernels that computes potential energy from $\mathbf{x}[i]$.
- ③ In a `ti.Tape(loss=potential)`, call the forward kernels.
- ④ Force on each particle is $-\mathbf{x}.grad[i]$.

Application 2: Differentiating a whole physical process

Life of a Taichi
Kernel
Yuanming Hu

Introduction

Python frontend

Intermediate
representation

Computation IR
Structural node IR

Sparse
programming

Differentiable
programming

Backends
Runtime system

Summary

10 Demos: `DiffTaichi` ($\mathbf{x}_{t+1}, \mathbf{v}_{t+1}, \dots$) = $\mathbf{F}(\mathbf{x}_t, \mathbf{v}_t, \dots)$

Pattern:

```
with ti.Tape(loss=loss):
    for i in range(steps - 1):
        simulate(i)
```

Computational history

Always keep the whole computational history of time steps for end-to-end differentiation. I.e., instead of only allocating

`ti.Vector.field(3, dtype=ti.f32, shape=(num_particles))` that stores the latest particles, allocate for the whole simulation process

`ti.Vector.field(3, dtype=ti.f32, shape=(num_timesteps, num_particles))`. Do not overwrite! (Use **checkpointing** to reduce memory consumption.)

Flattening-based reverse-mode AD²

Flattening-based reverse-mode AD with “good” loops

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR
Sparse programming
Differentiable programming
Backends
Runtime system
Summary

forward

$$y_i = \sin x_i^2$$

```
for i ∈ range(0, 16, step 1) do
    %1 = load x[i]
    | %2 = mul %1, %1
    | %3 = sin(%2)
    | store y[i] = %3
end for
```

Backward

```
for i in range(0, 16, step 1) do
    // adjoint variables
    %1adj = alloca 0.0
    %2adj = alloca 0.0
    %3adj = alloca 0.0
    // original forward computation
    %1 = load x[i]
    %2 = mul %1, %1
    %3 = sin(%2)
    // reverse accumulation
    %4 = load y_adj[i]
    %3adj += %4
    %5 = cos(%2)
    %2adj += %3adj * %5
    %1adj += 2 * %1 * %2adj
    atomic add x_adj[i], %1adj
end for
```

Note: Taichi uses global tensors as checkpoints,
so we need some recomputation.
(Megakernel has a cost in AutoDiff but still helps.)

representation

Computation IR
Structural node IR

Sparse
programming

Differentiable
programming

Backends

Runtime system

Summary

Not all backends are fully featured

Due to backend API limitations it may not be possible to implement certain features on all backends. For example, Apple Metal doesn't support 64-bit data types, so `ti.f64` is not available on Taichi's Metal backend.

Backend extension system

Backend extensions are used to describe the capability of each backend (beyond core functionalities). For example,

- ① `Extension::sparse`: sparse computation
- ② `Extension::data64`: 64-bit data types
- ③ `Extension::adstack`: stack-based AutoDiff
- ④ All backend extensions: ► [inc/extensions.inc.h](#)

Which backend supports what? ► [program/extension.cpp](#)

The LLVM backends

Computation IR
Structural node IR

Sparse programming

Differentiable programming

Backends
Runtime system

Summary

The CPU and CUDA code generators are based on LLVM (v10.0.0) ORCv2 JIT (CPU) and NVPTX backend (CUDA).

- Extremely portable: the LLVM CPU backend has no dependency
- Used as the fallback solution for all other backends
- Fully featured (i.e., support all extensions)
- Serve as references for other backends
- Has a (ideally) zero-cost runtime system (more on this later)
► [runtime/llvm/runtime.cpp](#)

Source-to-source backends

Life of a Taichi Kernel

[Python frontend](#)
[Intermediate representation](#)
[Computation IR](#)
[Structural node IR](#)
[Sparse programming](#)
[Differentiable programming](#)
Backends
[Runtime system](#)
[Summary](#)

Most backends do not take LLVM IR as input. In those cases we directly emit source code (i.e., source-to-source compilation).

- ① Metal ► [backends/metal](#)
- ② OpenGL ► [backends/opengl](#)
- ③ C99 ► [backends/cc](#)

Legacy CPU and CUDA backends

Taichi used to emit C++ and CUDA source code for CPU and CUDA backends as well. However, this solution is abandoned due to portability issues and long compilation time.

LLVM runtime system [►runtime/llvm](#)

Life of a Taichi
Kernel
Yuanming Hu

Introduction
Python frontend
Intermediate representation
Computation IR
Structural node IR

Sparse programming

Differentiable programming

Backends
Runtime system

Summary

Not really a runtime system...

Design tradeoffs

- One implementation should ideally serve for all LLVM-related backends
- The runtime code need to be compiled into LLVM IR and then linked against generated code
- We want to use something like C++ templates for each SNode
- ... but we cannot do “link-time template specialization” on LLVM IR \implies Inline as much as possible to “simulate” templates.

Runtime system written in C++ [►runtime/llvm/runtime.cpp](#) will be compiled to LLVM IR using clang by developers and ship together with the Taichi package.

Backends

Runtime system

Summary

- Language design and compiler engineering is a lot of fun!
- Keep it simple and practical.
- **Portability** is not an easy task.
- ~ 1 million downloads according to PePy, since Jan 2020.

Note

Many features of Taichi are developed by **my colleges at Taichi Graphics and the Taichi open-source community**.

Clearly, I'm just standing here talking 😊
